

A binary number is a combination of 1s and 0s. Its  $n^{\text{th}}$  least significant digit is the  $n^{\text{th}}$  digit starting from the right starting with 1. Given a decimal number, convert it to binary and determine the value of the the 4<sup>th</sup> least significant digit.

Example

number = 23

- Convert the decimal number 23 to binary number:  $23^{10} = 2^4 + 2^2 + 2^1 + 2^0 = (10111)_2$ .
- The value of the 4<sup>th</sup> index from the right in the binary representation is 0.

```
int fourthBit(int number)
{
    int binary[32];
    int i=0;
    while(number>0)
    {
        binary[i]=number%2;
        number/=2;
```

```
int i=0;
while(number>0)
{
    binary[i]=number%2;
    number/=2;
    i++;
}
if(i>=4)
{
    return binary[3];
}
else
return 0;
}
```

	Test	Expected	Got	
✓	<code>printf("%d", fourthBit(32))</code>	0	0	✓
✓	<code>printf("%d", fourthBit(77))</code>	1	1	✓

Determine the factors of a number (i.e., all positive integer values that evenly divide into a number) and then return the  $p^{\text{th}}$  element of the list, sorted ascending. If there is no  $p^{\text{th}}$  element, return 0.

Example

$n = 20$

$p = 3$

The factors of 20 in ascending order are  $\{1, 2, 4, 5, 10, 20\}$ . Using 1-based indexing, if  $p = 3$ , then 4 is returned. If  $p > 6$ , 0 would be returned.

```
long pthFactor(long n, long p)
{
    int count=0;
    for(long i=1;i<=n;i++)
    {
        if(n%i==0)
        {
            count++;
            if(count==p)
            {
                return i;
            }
        }
    }
    return 0;
}
```

	Test	Expected	Got	
✓	<code>printf("%ld", pthFactor(10, 3))</code>	5	5	✓
✓	<code>printf("%ld", pthFactor(10, 5))</code>	0	0	✓
✓	<code>printf("%ld", pthFactor(1, 1))</code>	1	1	✓
